
forced swap

$$e = q_{\text{swap}} - q_{\text{keep}}$$

resampling

$$d = q_{\text{free}} - q_{\text{keep}}$$

$$= (1 - p_1)\,(q_{\text{alt}} - q_{\text{keep}})$$

estimated from keep + alt
(the stratified drop d_s)

q: probability that the final answer differs from the greedy answer, estimated per branch from 32 continuations at T = 1.0.
